

Beyond Targets: Spatial Spillovers of Targeted Poor County Program

Jie Feng^{*}, Yuan Zhao[†], Kaixi He[‡], Dingwei Guo[§] and Zhengrun Chen[¶] ^{||} ^{**††}

Version: September 30, 2026

Abstract

This paper examines the spatial spillover effects of China's 2011 Targeted Poor County (TPC) program, which directs central government fiscal transfers to designated poor counties for investments in infrastructure, industrial development, and worker training. We extend a difference-in-differences framework to distinguish direct effects in target counties from spillover effects in adjacent non-target counties. Using household-level data from the National Fixed Point Survey and county-level statistical data, we find that the program increased household income and induced substantial rural labor reallocation from agricultural to nonfarm activities in both target and adjacent non-target counties. We further document three channels underlying these effects: improved transportation facilitating cross-county worker mobility, industrial expansion generating local agglomeration spillovers, and greater access to agricultural machinery services reducing agricultural labor demand. These findings show that place-based development policies can generate economically meaningful effects beyond target administrative boundaries.

Keywords: place-based development; spatial spillovers; rural labor reallocation; poverty alleviation

1 Introduction

Development policies are typically evaluated within target populations or regions, although spillovers to untreated areas may substantially alter their aggregate impacts (Kline and Moretti, 2014; Egger et al., 2022). In 2011, China launched a new round of the targeted poor county (TPC) program, directing fiscal resources to designated poor counties. Huang and You (2025) document higher farm and nonfarm income and rural labor reallocation from farm to nonfarm sectors within target counties. Evidence from other place-based policies suggests that spatial spillovers can be substantial, yet whether the TPC program generated similar labor reallocation in adjacent non-target counties remains largely unexplored.

In this study, we use China’s 2011 TPC program to examine its spatial spillovers in rural labor allocation. We extend the standard difference-in-differences (DID) framework by distinguishing target counties from adjacent non-target counties to identify spatial spillovers. Using the National Fixed Point Survey (NFPS) and China County Statistical Yearbook, we find that the program increased household income and shifted labor from farm to nonfarm activities in both target and adjacent non-target counties, indicating spillover effects beyond administrative boundaries.

We show that nonfarm activity spillovers work through three channels. First, improved transportation facilitates cross-county mobility of workers seeking nonfarm employment. Second, industrial expansion in target counties generates agglomeration spillovers that stimulate firm growth and employment in neighboring areas. Third, mechanization in target counties extends through cross-county machinery services, reducing agricultural labor demand and promoting nonfarm labor reallocation.

This paper directly extends Huang and You (2025) by documenting spatial spillovers of the TPC program to adjacent non-target counties. It also contributes to the place-based policy literature by showing that treatment effects can extend across administrative boundaries, underscoring the importance of accounting for spatial spillovers in policy evaluation (Ehrlich and Overman, 2020; Garin and Rothbaum, 2025). Ignoring such spillovers may lead empirical designs to misstate overall policy effects.

2 Policy Background and Conceptualization

The TPC program has undergone several rounds of county designation since the mid-1980s. Following [Huang and You \(2025\)](#), we focus on the 2011 round of the national TPC program, under which 832 counties were designated primarily according to local economic conditions.¹

Target counties received central fiscal transfers for infrastructure, industrial development, and worker training. [Huang and You \(2025\)](#) documents substantial growth in nonfarm income and working activities in target counties, accompanied by increases in local infrastructure investment, industrial development, and agricultural mechanization. We examine whether adjacent non-target counties experienced similar growth in nonfarm activities through three potential channels:

Transport and worker mobility. Improved transportation infrastructure in the target counties reduces travel and market-access costs and facilitates cross-county mobility of workers seeking nonfarm employment opportunities ([Morten and Oliveira, 2024](#)).

Firm agglomeration. Industrial expansion directly induced by the TPC program in target counties may generate agglomeration spillovers that stimulate firm growth and nonfarm employment in neighboring areas ([Ellison et al., 2010](#); [Greenstone et al., 2010](#)).

Agricultural machinery services. The TPC program promotes agricultural mechanization in target counties, while improved transportation facilitates the cross-county provision of machinery services to neighboring counties, reducing agricultural labor demand and promoting labor reallocation toward nonfarm activities ([Ma et al., 2024](#)).

3 Data and Empirical Strategy

3.1 Data

We include two datasets on the county and household levels in our main analysis. County-level variables are drawn from the China County Statistical Yearbook from 2006 to 2019 to align with [Huang and You \(2025\)](#). Household-level data come from NFPS, which is the largest rural household-tracking survey in China. We use the NFPS sample from 2006 to 2015 due to the restriction on data access. For the mechanism analysis, we add variables related with transportation network and

¹Earlier rounds were initiated in 1986, 1994, and 2001.

farmland terrain characteristics from [Davis et al. \(2025\)](#). The descriptive statistics are presented in Appendix Table [A1](#).

3.2 Empirical Strategy

We extend the standard DID specification by including non-target counties that share an administrative border with target counties to estimate spatial spillovers. For household-level outcomes, we estimate:

$$y_{it} = \beta^{target} target_{it} + \beta^{adj} adj_{it} + \delta_i + \lambda_{p,t} + \sum_{\tau} \gamma^{\tau} (pastRound^{\tau} i \times t) + \varepsilon_{it}, \quad (1)$$

where $target_{it}$ and adj_{it} indicate household i in target and adjacent non-target counties sharing the same administrative border with any target counties, respectively, in year t . δ_i and $\lambda_{p,t}$ denote household and province-year fixed effects. We further allow counties targeted in the 2001 or 2006 TPC rounds to follow round-specific linear trends. The coefficients β^{target} and β^{adj} capture the direct and spillover effects of the TPC program, respectively.

To estimate the dynamic effects and provide suggestive evidence on the parallel-trend assumption, we estimate the following event-study specification:

$$y_{it} = \sum_{k \neq -1} \beta_k^{target} D_{k,it}^{target} + \sum_{k \neq -1} \beta_k^{adj} D_{k,it}^{adj} + \delta_i + \lambda_{p,t} + \sum_{\tau} \gamma^{\tau} (pastRound_i^{\tau} \times t) + \varepsilon_{it} \quad (2)$$

where $D_{k,it}^{target}$ and $D_{k,it}^{adj}$ indicate the relative year k to year 2011 for households in target and adjacent non-target counties, respectively. The coefficients β_k^{target} and β_k^{adj} are relative to the omitted period $k = -1$; insignificant pre-treatment estimates support the parallel-trend assumption.

For county-level data, we use the same spillover-DID and event-study specifications but replace the household FE by county FE.

4 Results

4.1 Baseline Results

Table 1 reports the baseline estimates of the direct and spillover effects of TPC using the DID specification. Columns (1) to (3) show changes in local economic conditions at both the macro and household levels. The program significantly increased GDP per capita, farm income, and nonfarm income in target counties by approximately 15.0%, 13.5%, and 18.8%, respectively, with corresponding increases of 10.7%, 9.6%, and 10.7% in adjacent non-target counties.

Columns (4) to (6) further decompose these economic changes through shifts in rural labor allocation. In target counties, farm labor input days declined by approximately 9.4%, nonfarm labor input days increased by 23.5%, and the county-level share of rural nonfarm workers rose by 12.2%. Similar changes occurred in adjacent non-target counties, where farm labor input declined by 5.4%, nonfarm labor input increased by 19.1%, and the rural nonfarm worker share rose by 11.1%. These results indicate substantial spillover effects on labor reallocation from farm to nonfarm activities in adjacent non-target counties.

Figure 1 presents the corresponding event-study estimates. The pre-treatment coefficients are close to zero, providing support for the parallel-trends assumption, while the post-treatment estimates are broadly consistent in magnitude with the baseline DID results.

4.2 Mechanism and Heterogeneity Analysis

In Tables 2 and 3, we examine three potential channels through which the TPC-induced changes in target counties may have extended to adjacent non-target counties and contributed to the observed spillover effects.

Table 2 first examines the outcomes associated with the three proposed channels. Columns (1) and (2) show that highway and railway density increased by 20.9% and 11.2% in target counties, consistent with the TPC program’s investment in transportation infrastructure. Columns (3) and (4) show that industry-sector value added and the number of large industrial firms increased by 15.5% and 12.2% in target counties. Similar increases are observed in adjacent counties, at 8.5% and 4.9%, respectively, consistent with agglomeration spillovers in local industrial activity.

Columns (5) and (6) show that machinery ownership increased by 5.9% in target counties,

while machinery use rose by 10.0% in target counties and 8.3% in adjacent counties. The increase in machinery use in adjacent counties was not accompanied by a corresponding rise in machinery ownership. This finding suggests that machinery acquired in target counties from TPC may have been accessed through cross-county service provision (e.g., rental services).

Figure 2 presents the corresponding event-study estimates, with generally insignificant pre-treatment coefficients and post-treatment estimates broadly consistent with the DID results.

We next use Table 3 to provide more evidence on the three proposed channels by examining how the labor-reallocation effects vary with relevant baseline conditions. In Columns (1) to (3), the interactions with baseline highway density, railway density, and the number of industrial firms are significantly negative for both target and adjacent counties, indicating stronger shifts toward nonfarm labor where transport infrastructure and industrial development were initially weaker. Columns (4) and (5) show smaller increases in household nonfarm labor input in areas with greater farmland ruggedness and fragmentation,² which constrain machinery use (Afridi et al., 2023; Ma et al., 2024). These findings are further consistent with the three proposed mechanisms.

In Appendix B, we show heterogeneity in the labor-reallocation effects by household characteristics. We find the effects are stronger among households with a larger share of working-age members and among those with greater pre-existing engagement in family business, with similar effects in target and adjacent counties. These heterogeneous effects suggest that household labor availability and prior engagement in nonfarm activities shape the extent of direct and spillover effects following the policy.

4.3 Robustness Checks

Second-order spillovers. In Appendix Tables C1 and C2, we examine whether spillovers extend beyond directly adjacent counties by adding second-order neighboring counties, defined as non-target counties adjacent to first-order neighboring counties but not directly adjacent to target counties, and find no significant effects beyond directly adjacent counties.

Confounding policies and regional characteristics. In Appendix Tables C3 and C4, excluding counties affected by concurrent place-based policies (contiguous destitute areas, and old

²Farmland ruggedness is measured at the county level as the standard deviation of within-county elevations, following Davis et al. (2025). Farmland fragmentation is measured at the household level from NFPS as the inverse of the average farmland area per plot, such that a higher value indicates more fragmented farmland.

revolutionary base areas) or distinctive regional characteristics (Xinjiang and Tibet, and ethnic minority counties) leaves the estimates largely unchanged.

Selection into TPC. In Appendix Tables C5 and C6, allowing differential linear trends by pre-treatment economic, infrastructure, and agricultural conditions produces similar results.

Anticipation effect. In Appendix Figures C1 and C2, placebo treatment years prior to 2011 yield coefficients close to zero, providing additional evidence against pre-existing trends and anticipation effects.

5 Conclusion

This paper extends Huang and You (2025) by examining the spatial spillover effects of China’s 2011 TPC program on rural labor allocation. We find that the program increased household income and shifted labor from agricultural to nonfarm activities not only in target counties but also in adjacent non-target counties. The evidence suggests that improved transportation, industrial expansion, and greater access to agricultural machinery services contribute to these spillover effects. Overall, the findings show that the effects of place-based development policies can extend beyond directly target regions, highlighting the importance of accounting for spatial spillovers in policy evaluation.

Railway density	11.14 (19.50)	28.61 (55.78)	42.34 (88.04)
Terrain ruggedness	1,407.16 (965.39)	1,045.09 (1,012.95)	661.59 (670.08)
Group size	748	661	976

Note: This table reports the mean of each variables before 2011. Standard deviations are in parentheses. The number of target counties is less than 832 due to the missing information from the County Statistical Yearbook.

B Heterogeneity Analysis

To better understand the distributional consequences, Appendix Table B1 examines heterogeneity in the effects of the TPC program on household nonfarm labor input. Column (1) shows that the interaction with the family labor force share is significantly positive for both target and adjacent counties, indicating stronger increases in nonfarm labor input among households with a larger share of working-age members. Column (2) shows that the interaction with an indicator for family business as the primary income source is also significantly positive in both groups. This suggests that households more engaged in family business experienced larger increases in nonfarm labor input following the TPC program. Overall, the results indicate that both the direct and spillover effects on labor reallocation vary systematically with household labor availability and pre-existing engagement in nonfarm economic activities.

Table B1: Heterogeneity Analysis
